Running VNC on Windows

Step 1: Open Putty and ssh directly into Prince directly. If you are off-campus this technique won't work.

Step 2: Run the below command to gain access to a compute node

```
$qsub -I
```

Note: -I is caps i.

You should see something like the below text. Getting access to a compute node takes time (a few seconds to a few minutes based on how busy the cluster is)

```
---------------------------------------------------------------------------------------------------------------------
WARNING no memory limit specified, assuming <2GB/CPU (2gb total)
qsub: waiting for job 8756849 to start
qsub: job 8756849 ready
---------------------------------------------------------------------------------------------------------------------
```

Step 3: Once you get access to a compute node you need the IP address of that node. For that run the command

```
$hostname -i
```

You should see something like the below text in Putty.

```
10.0.254.174
```

Step 4: Run the command

```
$vncserver
```

You should see some text like the text below.
New 'compute-4-12.local:1 (trc311)' desktop is compute-4-12.local:1

Starting applications specified in /home/trc311/.vnc/xstartup
Log file is /home/trc311/.vnc/compute-4-12.local:1.log

---------------------------------------------------------------------------------------------------------------------
Here you can see the login node port which is 1. (local:1 this could also be zero). Make a note of this because it is needed for the next step. In case you haven't set a password for vnc, you will be asked to create a password for security purposes. You can alternatively set it or change it using the command $vncpasswd.

Step 5: Change some options in Putty now. Click on the Putty icon on the top left corner of the Putty window. Go to Change Settings. Now go to Connections and then SSH option. Select Tunnels. Here you enter a source port (any number greater than 1024) and the destination would be the IP address of the compute node followed by the login port i.e. 590x where X is either 1 or 0. Once you've entered the source port and destination click on Add and then Apply. The destination address should look like 10.0.xxx.xxx:590x. Remember to put a colon (:) between ip address and port number.

![PuTTY Reconfiguration](image)

Step 6: Now run the vncviewer of your choice. Enter the vncserver details. I have used tightvnc here but you can choose the vnc of your choice. You enter the remote host address as

    localhost:<source_port>

Here the source_port is the source port you entered in your Putty settings. Once you run that a popup will ask you to verify login. Here you enter
your vnc password that you set before.

You are good to go now. You can see a display and run the module of your choice now.

Running VNC on Linux

Step 1: ssh into Prince

Step 2: qsub -l

You will be assigned a compute node for that particular job.

Step 3: Setting up the VNC

a) Enter the command:
   
   $vncserver

   New 'compute-8-7.local:1 (trc311)' desktop is compute-8-7.local:1

   Starting applications specified in /home/trc311/.vnc/xstartup

   Log file is /home/trc311/.vnc/compute-8-7.local:1.log

b) If you haven’t set up a vncserver before it might prompt you to setup a password. Enter the password and remember it. Or you can set it up using the command $vncpasswd

c) Type the command

   $hostname -i

   This should return the ip address for your compute node.

   10.0.254.76
d) Once the vncserver has been setup, port forwarding has to be done. For this first go to a new line of the terminal and then you press the shift key + tilde (~) at once followed by shift key + C

ssh>

Something like the above should be seen in your terminal. If not go to a new line in the terminal and repeat the d)

Now type the following:

ssh> -L<port_no>:<compute node ip address>:590x

Here, the port_no has to be any number greater than 1024. Make sure the port is not being used by another vncserver, otherwise you will get an error. In 590x, the x is the login port of localhost i.e. 1 or 0. Make sure there are no spaces between the forwarding command.

Step 4: Now go to your VNC application and enter the server information as local host information.

localhost:<port_no>

For some applications ssh might be auto checked, remember to uncheck that option. Once vnc session starts it might prompt you for a password which should be the password you entered while setting up the vncserver.

Now open the terminal on the display i.e. the compute node and run the module that you need.
