The following script is an example psychopy script. A lot of the script is wrapper to make life easy for you (e.g., so you don't to start this script multiple times in a single session; so you don't accidentally overwrite your data). The core of the script, which updates the image shown on the display and records all buttons pressed, happens in the `run` function. Note that this assumes you create the stimuli and presentation indices ahead of time, saving them as numpy arrays (.npy).

This script can be found as a github gist [here](https://github.com). It is based on *experiment.py* from my spatial frequency preferences experiment.
